WPF Blogs

- Josh Smith Blog
- WPFpedia
- Mike Taulty's Blog

Introduction

- What is WPF?
 - A Graphical User Interface Technology
 - Desktop
 - Little brother Silverlight is used for web applications
 - Uses Markup and Code
 - Together or separately, much like ASP.Net
 - Easy to produce different styles
 - Web browser like navigation and placement
 - Traditional forms
 - Animated Graphics

Markup

- XAML
 - eXtensible Application Markup Language
 - Tags are names of .Net 3.5 classes
 - Attributes are class properties and events
 <Grid>
 - <Ellipse Fill="blue" />
 - <TextBlock>

Name: <TextBlock Text="{Binding Name}" /> </TextBlock>

</Grid>

Code Behind

- Often, code provides processing for control events, bound in XAML, like this:
 - XAML in Window.Xaml

<Button

x:Name="button"

Width="200"

Height="25"

Click="button_Click">Submit</Button>

– C# code in Window.Xaml.cs

Void button_Click(object sender, RoutedEventsArgs e) {
 MessageBox.Show(...) }

C# Wizard

Physics Lab 201		Hello from the Main Page. This is so	ome obscure and not very int	eresting text, designed to keep you busy.	
This is some text about the physics laboratory.					
You can have as many paragraphs as you like. You may even enclude	Budget				
you like. You may even enclude multiple sentences like this one.	Personnel				
Status:	Mentoring				

Panels

- Layouts, like the previous page can use:
 - Canvas
 - Simplest, placement relative to two edges
 - StackPanel
 - Horizontal or vertical stacking
 - Grid
 - Uses rows and columns
 - Unsized elements fill Grid cells
 - DockPanel
 - Dock to top, right, bottom, left, and all else fills remaining space
 - WrapPanel
 - Horizontal stacking with wrap on overflow
 - All of these can be nested, any one in another

Vector Graphics

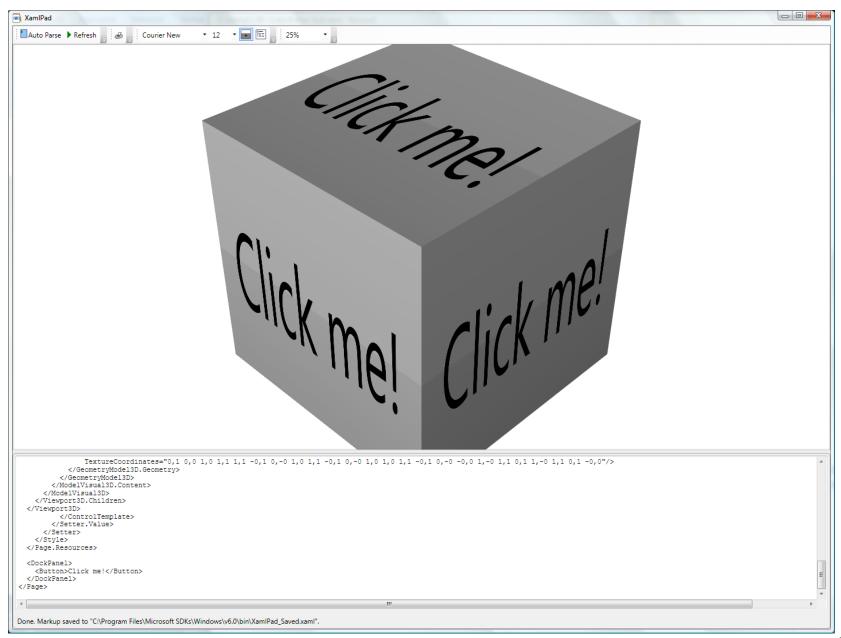

- In WPF there is only (usually) one window
 - Controls are not windows!
 - No handles really, no handles
 - A button is a shape with border, fill, text, animation, and events, like click.
 - There is a Button class, but it is not a .Net control in the traditional sense nor an ActiveX control.
 - Just markup, lines, fills, and events.

Parse Tree

- XAML gets rendered into a parse tree, just like
 XML it is XML
 - Inherited properties are based on parent child relationships in the markup tree
 - Events bubble based on those relationships as well
 - You have direct and simple control over that structure
 - The world is yours!

What Makes WPF Unique?

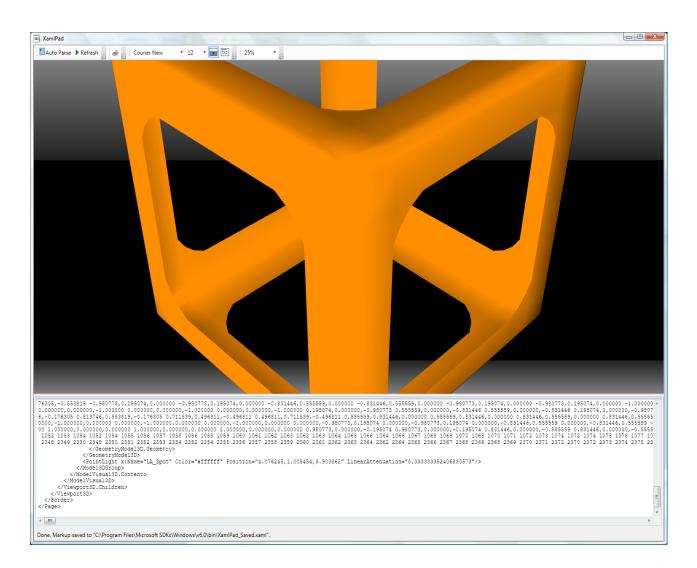

- Vector Graphics with Parse Tree Structure derived from markup
- Routed Events bubble up the parse tree
- Pervasive Publish and Subscribe Model
 - Data Binding
 - Dependency Properties
- Layered on top of DirectX
 - Strong 2D and 3D graphics
 - Animation
- Layout and styles model similar to the best of the web

Routed Events

- WPF maps markup elements to UIElements, which derive from ContentControl
 - That means that almost everything can hold content – only one thing unless it's a panel.
 - How does a mouse click *event* on any one of a control's content elements get *routed* to the control?
 - By walking the XAML parse tree until it finds a parent that handles that event.

Adding Event Handlers

- You will find that property sheets show events as well as properties
 - click on the lightning bolt to see the event sheet.
 - You subscribe by clicking on an event entry.
- You can also add event handlers quickly in XAML:
 - Go to the XAML, type a space after the tag for the element you want to handle the event
 - That gets you a context menu (via intellisense) and you just double click on the desired event, which adds an event attribute

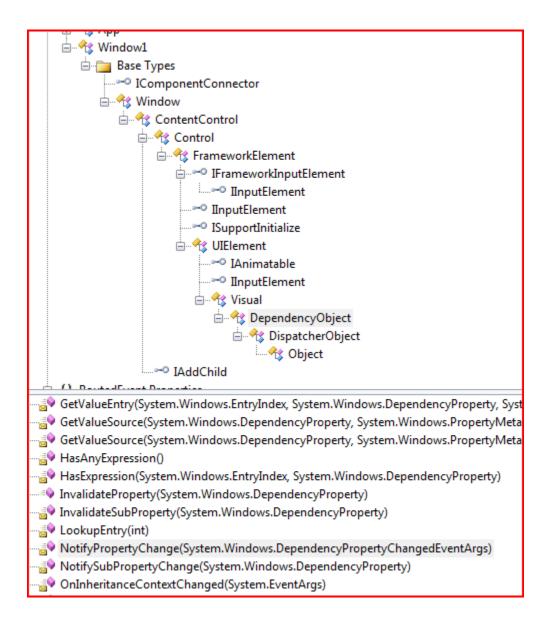

Attached Properties

- Buttons, ListBoxes, Images, etc., do not have Dock properties.
- However, when you place one of these in a DockPanel, you find that it has had Dock properties attached.

<Image Source="./help.png" *DockPanel.Dock="Top"* Height="213" ImageFailed="Image_ImageFailed" />

DependencyObject Class

- Attached properties work because all WPF controls derive from the DependencyObject class.
 - DependencyObject class supports adding an arbitrary number of dependency properties.

Dependency Properties

- A Dependency Property is a property that is registered with the WPF Dependency property system. Two uses:
 - Backing an object property with a dependency property, provides support for databinding, styling, and animation. Examples include Background and Fontsize properties
 - Creating attached properties. Attached properties are properties that can be set on ANY DependencyObject types. An example is the Dock property.
- You can find an example of the definition and use of a custom Dependency Property <u>here</u>.
- Dependency Properties are a Publish and Subscribe system.

Dependency Property Links

- Josh Smith's Blog
- Switch on the Code Blog
- Learn WPF site

Property Syntax

- Two syntax forms:
 - XAML attribute:
 -
sutton ToolTip="Button Tip />
 - Property Element Syntax:
 - <Button>
 - <Button.Background>
 - <SolidColorBrush Color="#FF4444FF" />
 - </Button.Background>
 - Some Button Text
 - </Button>

Markup Extensions

 Sometimes you need to assign a property from some source at run-time. For that you use Markup Extensions:

<Button Foreground="{x:static SystemColors.ActiveCaptionBrush}" > Some text </Button>

Inline Styles

- Collections of property values:
 - <Button.Style>
 - <Style>

```
<Setter Property="Button.FontSize" Value="32pt" />
<Setter Property="Button.FontWeight" Value="Bold" />
</Style>
</Button.Style>
```

Named Styles

- Collections of property values:
 - <Window.Resources>

<Style x:Key="myStyle" TargetType="{x:Type Control}"> <Setter Property="FontSize" Value="32pt" /> <Setter Property="FontWeight" Value="Bold" /> </Style> </Window>

Binding

- Binding infrastructure allows you to set up a one-way or two-way updating of property values that happens when the source changes.
- This requires two things:
 - A dependency object
 - Has its own dispatcher thread
 - Support for INotifyPropertyChanged interface

Binding

- Objects that implement INotifyPropertyChanged interface raise events when the property has changed.
- Data binding is the process of registering two properties with the data binding engine and letting the engine keep them synchronized.
- You will find an example in the Wpf_AttachedProperties demo code.

Binding Links

- MSDN Article by John Papa
- <u>CodeProject article by Josh Smith (part of a</u> <u>tutorial series)</u>
- Bea (Costa) Stollnitz

Control Templates

- With Control Templates you can change the look and feel of existing controls and support making your own controls:
 - <Button.Template> <ControlTemplate> <Grid><Rectangle /></Grid> </ControlTemplate> </Button.Template>

Navigation

- You can use instances of the Page and Frame classes to set up a navigation structure resembling web applications.
 - Pages go in NavigationWindow instances and Frames go in Windows and Pages.
 - This is a good alternative to tabbed displays.

Special Classes

- ContentControl
 - All UIElements derive from this.
 - Content can be text, a tree of elements, or a .Net object which can be displayed using a data template
- Dependency Object
 - Derives from Dispatcher Object
 - Supports data binding, styling, animation, property inheritance, and property change notifications
- WindowsFormsHost
 - Supports hosting controls based on HWNDs

Special UIElements

- ViewBox
 - Resizes content to fit available space
- UserControl
 - Way to build custom controls as collections of elements on a panel
- Animatable
 - Provides hooks for DirectX to change elements properties over time, e.g., position, size, color, ...
- FlowDocument
 - FlowDocumentScrollViewer
 - FlowDocumentPageViewer
- MediaElement
 - Play media on load or on request, e.g., wma, wmv, mp3, ...

End of Presentation
